Subject: Connecticut Population Projections - June, 1989

This report contains population projections, including age and sex distributions which supercede those promulgated in December, 1984. These projections should be utilized by state agencies in Connecticut in their planning and policy activities. Others are encouraged to use these population projections to provide uniformity and standardization of planning assumptions. The methodology for the preparation of projections has been revised, with significant changes in migration methodology. Details of the methodology are contained within the report.

The populations are projected by age and sex for each municipality, region and the State by five year periods from 1990 to 2010. In addition to the projections being made available through this published report, the entire report, with the birth, death and migration data used to develop these projections is available on diskette.

The cooperation and funding provided by the Connecticut Statistical Analysis Center, Management and Justice Planning Division, Office of Policy and Management is greatly appreciated. We express our appreciation to the Connecticut Departments of Health Services, Education and Motor Vehicles, which provided both information and assistance in the preparation of these projections. Additional assistance in reviewing and clarifying the new population projection methodology was provided by a Technical Advisory Committee for Population Projections.

Our appreciation is also extended to the Regional Planning Organizations and municipalities that provided commentary on the projections. This regional and local perspective was especially helpful in considering special population groups within specific municipalities. A summary of the review comments is contained within the report.

The data that was used to develop migration trends had to be available for every municipality on an annual basis and it had to provide a direct measure of population movements by age. By using these criteria, other measures of migration, such as housing construction, could not be used. Moreover, zoning, economic trends or a municipality's growth management practices were not used as limiting factors in these projections. Instead these projections reflect the composition of future populations if the demographic trends identified between 1980 and 1987 were to continue.

We believe these age and sex distributions of the population projections represent the best current determination of future population distributions of the State of Connecticut, its regions and municipalities. As a result of our new projection methodology, data collection, and computer processing, this office will be now able to update these projections periodically, thereby keeping the data and assumptions related to births, deaths and migration current.

Specific inquiries concerning these population projections or their use may be addressed directly to James G. Palma, Jr., Connecticut Census Data Center, Comprehensive Planning Division, Office of Policy and Management. Staff may be contacted at (203) 566-8285.

Introduction

This report presents resident populations for Connecticut, its regions and municipalities from 1980 through 2010. The 1980 population figures are actual counts from the U.S. Census of Population and are presented by age and sex. The 1985 population figures are estimates by age and sex developed by the Office of Policy and Management. The 1990 through 2010 population figures (calculated at five-year intervals) are projections by age and sex. All projections have been prepared by the Office of Policy and Management.

The projections were produced using a new methodology that addresses the dynamics of people moving in and out of Connecticut municipalities. Along with up-to-date birth and death data, the migration indicators are available for each municipality annually which permits a more frequent update of the projections.

The projections presented differ from forecasts in that they are the result of a mathematical projection model given explicitly stated assumptions. These assumptions emphasize trends present in the data (between 1980 and 1987), not anticipated or desired trends. The birth and death assumptions are held constant during the entire projection period. The migration assumptions are held constant through 1990; slight adjustments are made after 1990. The resulting projections represent a consistent set of data for all municipalities that were developed using a consistent methodology and assumptions. The individual municipal projections were then aggregated to regional and statewide summaries. Small, often unforeseeable, changes in economic, social, or demographic conditions in any single municipality can and will cause future population change to deviate from the projected trends.

Although only one set of projections was developed by the Office of Policy and Management, this does not imply certainty about the future course of events. Preparing population projections for municipalities and geographic areas with small populations is difficult. The small size of these areas makes them especially sensative to the many forces which may impact the population projections. Some of these forces are: changes in land uses, changes in zoning and zoning holding capacities, economic conditions, housing, building construction, environmental conditions, changes in transportation patterns and services, etc. However, the population projections are presented for small population areas to at least indicate present trends in population.

These population projections utilize a mathematical projection model known as the cohort-component method. This method permits separate assumptions to be made for each five year age group and by sex for each of the components of population change: births, deaths, and migration. These projections are the first to incorporate age and sex specific municipal net migration developed from annual administrative data. These data are used in combination with the 1980 decennial census data as a basis for projecting future migration.

A major effort has gone into developing both a new projection methodology and using it to produce new population projections. These new population projections will be used until they can be calibrated with the age and sex breakdown of the 1990 decennial census, which should be available in spring or summer of 1991. After that comparison is completed, new assumptions will be made to reflect the actual 1990 census counts. The projection methodology itself should not have to be changed. The new method will accept new assumptions and data whenever the birth, death or migration trends change.

In using these population projections, please consider the following points:

- These projections illustrate what may happen to the population over the next 21 years, if similiar birth, death and migration patterns continue as they did between 1980 and 1987. Very recent or known future development or growth management activities are not reflected in the projections.

- These figures are not the result of desired or anticipated economic or housing conditions, nor restricted by current or future zoning regulations. They are the result of a demographic (an age-sex cohort) population projection model.

- The birth, death and migration patterns will change as a result of future economic, housing or zoning developments. These new birth, death and migration patterns will be used in making future projection updates. It has been recommended that the projections henceforth be updated every other year.

- Our previous series of population projections were done in 1982, utilizing trends from the late 1970s to early 1980s. These new population projections provide figures reflecting the 1980 through 1987 trends, and extend the projection period ten years, to the year 2010.

- There is a large effort involved in developing a new projection methodology, reviewing the methodology and then making improvements to the methodology. Because of this, it was decided that OPM would prepare and issue these projections prior to the 1990 Census. This will allow planners, policy makers and business users to become familiar with the new methodology and data. Further improvements will be considered when the results of the 1990 decennial census become available, two years hence.

Projection Highlights

Statewide Projections

According to the projected data, Connecticut's population will continue its slow steady growth across most of the state, through the year 2010. (See Chart 1 and Table 1). The percent increase in population per year is expected to average less than one-half percent (0.5%), between 1980 until 2010. The tremendous growth period of the 1960's, when the state's population was growing at a 2% annual rate, is not projected to be repeated.

The growth between 1980 and 1985 was 2.6% (note this is a five year growth rate). This is an considerable increase over the five year rates during the 1970's. The population growth rate in the current period, 1985 to 1990, has been estimated at 3.4%, which is the expected to be the largest growth period in the next 21 years. The first half of the 1990's is projected to grow at a steady 3.0%. The five year growth rate is expected to drop off to a 1.6% increase by the end of this century.

CHART 1 below is a comparison of the 1989 Connecticut Office of Policy and Management (1989 OPM) population projections, the previous set of OPM projections (1982 OPM), the latest projections from the U.S. Bureau of the Census (1988 Census), and the population estimates from the Connecticut Department of Health Services (Annual DHS).

TABLE 1

Comparisons of Population Projections and Estimates

Year	Office of Policy and Management 1989	Office of Policy and Management 1984	Bureau of the Census 1988	Department of Health Services Estimates
1960[1]	2,535,234	2,535,234	2,535,234	2,535,234
1970[1]	3,032,217	3,032,217	3,032,217	3,032,217
1980[1]	3,107,576	3,107,576	3,107,576	3,107,576
1985	3,190,250	3,179,600	3,189,000	3,198,200
1988				3,326,400[2]
1990	3,299,050	3,258,200	3,279,000	
1995	3,399,600	3,324,000	3,376,000	
2000	3,455,600	3,380,000	3,445,000	
2005	3,487,150		3,493,000	
2010	3,499,800		3,532,000	

[1] Actual counts from decennial census.

[2] Latest population estimate dated July 1, 1988; however, data used to prepare estimates were dated calendar year 1987.

Sources: Connecticut Population Projections, Office of Policy and Management, 1982 and 1989 (Series 89.1); Annual Population Estimates, Connecticut Department of Health Services, 1981 to 1988; and Population Projections for States, U.S. Bureau of the Census, 1988.

Briefly, the differences between these figures are in the methods of calculating migration. The Census Bureau uses address changes between states from IRS tax returns between 1978 and 1986. The annual population estimates averages two methods: one is based upon changes in school enrollments; the second applies a modified persons per household to all new housing permits. The 1982 OPM method relied on the average affect of natural change from 1978 to 1982, compared to the actual 1980 decennial census counts. The 1989 OPM projections relies on changes in age/sex specific school enrollments, changes in drivers licenses issued, and changes in medicare enrollments between 1980 and 1987.

Referring to CHART 2, one can see the baby boom generation moving from their late twenties, thirties, and forties age groups in 1990 to the forties, fifties, and sixties in 2010. The ten year age group that is expected to grow the most is the fifties, with an increase of 75%. This is followed by persons in their sixties, with a 40% increase between 1990 and 2010. The largest decrease is expected with the thirty year olds, which is expected to decline 30%. The next largest decline are children under 10. They are projected to decline 15% between 1990 and 2010.

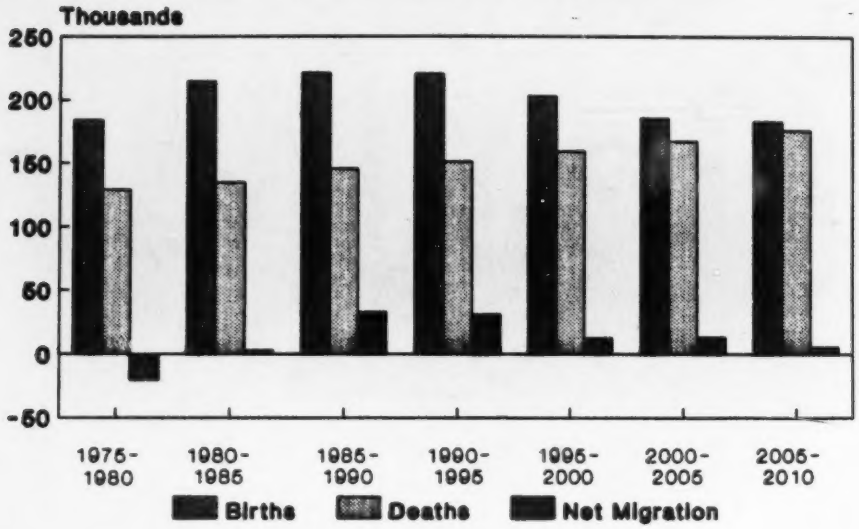
Prepared by: Connecticut Census Data Center, Office of Policy and Management, 6/89.

Natural Change

Natural change is the difference between births and deaths during a set period of time. As seen in CHART 3, the number of births is increasing on the average of 500 births per year between 1975 and 1990. After the peak between 1985 and 1990 of 221,000 births, the number is expected to decrease by 400 births per year through the year 2010. At the same time, the number of deaths are projected to steadily increase by 300 per year between 1980 and 2010. By the year 2010, the number of births and deaths almost balance the effects of one another.

CHART 3

CONNECTICUT POPULATION PROJECTIONS
Components of Change



Source: Connecticut Population Projections, Series 89.1

Prepared by: Connecticut Census Data Center, Office of Policy and Management, 6/89.

Net Migration

Net migration is the net effect of the movements or migration of people. In TABLE 2 for example, the net migration of -20,000 between 1975 and 1980 was the result of 325,000 persons moving into Connecticut and 345,000 persons leaving Connecticut (not to mention the many people who moved within the state).

Again referring to CHART 3 and TABLE 2, it is clear that Connecticut has been experiencing a major change in net migration. After some years of being a state with net outmigration, Connecticut residents are now more likely to move into and stay in Connecticut. However, this trend of net inmigration is projected to decrease after 1995. Around the beginning of the 21st century, approximately 2,500 more people per year will move into the state than move out.

TABLE 2

Components of Change of the Population Projections

Time Period	Births	Deaths	Net Migration	Ending Population	Natural Change	Numeric Increase
1975 to 1980[1]	183,950	129,350	-20,100	N/A	54,600	N/A
4-1-80				3,107,576		
4-1-80 to 6-30-80	9,600	6,300	N/A	N/A	3,300	N/A
1980 - 1985[2]	214,800	135,050	2,950	3,190,250	79,050	82,650
1985 - 1990[2]	221,200	145,800	33,350	3,299,050	75,400	108,800
1990 - 1995[2]	220,400	151,150	31,350	3,399,600	69,200	100,550
1995 - 2000[2]	202,650	159,450	12,800	3,455,600	43,200	56,000
2000 - 2005[2]	185,650	167,500	13,400	3,487,150	18,150	31,550
2005 - 2010[2]	182,850	176,000	5,750	3,499,800	6,900	12,650

[1]Time periods start on January 1st and end on December 31st.
[2]These time periods start on July 1st and end on June 30th.

1985-2010 data -- Connecticut Population Projections, Series 89.1.

Note: Numbers may not add due to rounding.

Planning Regions

The population projections for the fifteen Planning Regions in Connecticut illustrate that the population is projected to change differently across the state. (See TABLE 3). The Capitol, South Central, and Central Naugatuck Valley planning regions will grow the most between 1980 and 2010, an increase of 77,000, 73,000, and 58,000 persons respectively. Over one-fifth of the state's population will continue to reside in the Capitol planning region.

The South Western planning region is expected to grow about 2% from 1980 until 2000. Then it is projected to decline in population to the year 2010. The overall loss is approximately 6,000 in population between 1980 and 2010.

The Northeastern Connecticut, Windham, Central Naugatuck Valley and Housatonic Valley regions have the largest percent increase at 24%, 21%, 20% and 20% respectively.

TABLE 3

Population Projections By Planning Region
(in thousands)

Planning Region	1980	1990	2000	2010	1980 - 2010 Percent Increase	1980 - 2010 Numeric Change

Source: Connecticut Population Projections, Series 89.1

Median Age

The age at which half the population is above a figure, while the remaining half of the population is below that age, is called the median age. To use a simplistic example, if out of 100 people, fifty were under the age of 30 and the remaining fifty were over 30, then the median age is 30. Median age figures are useful in making quick age comparisons between municipalities or other geographic areas, such as Health Service Areas (HSAs). TABLE 4 contains the median age figures for the five Connecticut HSAs, which are used by Area Agencies on Aging.

All five areas show a considerable increase in the median age. This indicates that the population is expected to age throughout Connecticut, with the oldest age area switching from the Southwestern HSA in 1980, to the Northwestern HSA by 2010.

TABLE 4

Median Age By Health Service Area

Health Service Area	1980	1990	2000	2010	1980 - 2010 Percent Change
Southwestern	34.1	36.5	39.7	42.1	23%
South Central	31.8	34.8	38.3	41.0	29%
Eastern	29.6	33.2	37.1	40.3	36%
North Central	31.9	35.1	38.6	41.4	30%
Northwestern	32.4	35.3	39.0	42.5	31%
Connecticut	32.0	35.0	38.6	41.5	30%

Note that due to slight differences in statistical methods of calculating the median age, the figures presented in this report for 1980 may differ slightly from figures prepared by the U.S. Bureau of the Census for municipalities in 1980.

Methodology

Population projections were prepared for each of the 169 cities and towns in Connecticut. Population projections were not prepared for the non-coterminous cities and boroughs. The projections were projected using a cohort-component method with extensive modifications for net migration. The projections are for 1990 through 2010 in five year intervals, with population figures showing five year age groups by sex for each municipality. These municipal projections were then aggregated to produce regional and statewide projections.

The projections are based upon a variety of data gathered from 1980 to 1987 with the 1980 decennial census as a base. Actual birth and death data were provided by the Connecticut Department of Health Services, with net migration indicators provided as follows: school enrollment provided by Connecticut Department of Education; licensed driver data provided by Connecticut Department of Motor Vehicles; and medicare enrollment data provided by U.S. Health Care Financing Administration.

Description of the Cohort-Component Method

Among the various population projection methods available, the cohort-component method is widely accepted. This acceptance is largely due to its ability to have separate assumptions on the three major "components" of population change: births (or fertility), deaths (or survival) and migration. In addition, this method allows for separate assumptions (or conditions) to be held for specific age groups, called "cohorts." There is a further separation made so that female cohorts and male cohorts are established. This versatility enables the projections to be reponsive to the different changes among the age/sex groups within each municipality.

For example, college age men and women tend to move away from their home town and into municipalities where colleges are located. On the other hand, young children would likely be moving into many municipalities along with their parents who moved due to different housing and/or job opportunities.

The versatility of the cohort-component method is also a drawback. Given five year age/sex cohorts, there must be an historical account for each cohort. That requires historical files for each of 36 different five year cohorts (18 female age groups and 18 male age groups) for each municipality. Therefore, in order to be versatile and provide different assumptions for each age/sex cohort, it is then necessary to locate reliable historical data that can be used to develop fertility, survival, and net migration assumptions for each of the 36 cohorts (in total there are 81 historical data files: 9 fertility, 36 survival and 36 net migration indicators for each municipality).

The cohort-component method as used in these projections, divided each municipal population into 36 different five year age/sex cohorts. The time span of the age/sex cohort must be the same as the projection period. This set of projections provides population projections every fifth year, therefore the cohorts time span was divided into five year age groups.

Once the population of each municipality was divided into the necessary cohorts, then the historical data files (mentioned above) were collected, verified, and adjusted to correspond to each cohort. Next these historical files were converted into five year rates.

The procedure for creating rates begins on page 12. Once the rates were created for each corresponding cohort, they were held constant. The one exception being migration rates after 1990, see page 18. (Note: Holding rates constant did not result in having the same number of births, deaths, or migration occur every five year period. Instead, the projected number of births, deaths and migration were a result of the combined effects of the rates for a specific age group along with the current population to which the rate was being applied. See example of births located on page 16.)

The next step was to apply the appropriate rates to each of the 36 cohorts for each municipality. The result was a new set of 36 age cohorts that are now five years older. This was continued at five year intervals until the year 2010 was reached.

This process can be expressed by the following notation:

$$Population_{projected} = Population_{current} \times Survival\ Rate \times Net\ Migration\ Rate$$

The above expression does not account for births. Therefore, a separate expression was developed only for women of childbearing ages. Actual birth data indicated that women begin having children as early as age 10 and as late as age 54 in Connecticut. Therefore, fertility rates were developed for women between the ages of 10 and 54. Further details on fertility rates are located in the discussion on Births, pages 12 and 16. Below are the expressions used to describe how births were projected.

$$Projected\ Number\ of\ Females\ to\ be\ Born =$$

$$Women_{childbearing\ cohort} \times Fertility\ Rate\ for\ Female\ Births_{\ childbearing\ cohort}$$

$$Projected\ Number\ of\ Males\ to\ be\ Born =$$

$$Women_{childbearing\ cohort} \times Fertility\ Rate\ for\ Male\ Births_{\ childbearing\ cohort}$$

This process is repeated for all the childbearing age groups in five year intervals. All of the births within each five year period are placed in the first cohorts (0 to 4), keeping males and females separate.

One more adjustment was made to the general formula, to account for high concentrations of persons in group quarters (e.g. prisoners, students in dormitories, etc.); off base military personnel and their families (e.g. throughout Groton); and off campus college students (e.g. within New Haven for Yale University, Southern Connecticut State University and Albertus Magnus College).

Simply stated, these populations do not change in the same manner as the general population. Therefore, selected populations according to age/sex cohorts were held constant. More details on how these populations were handled are presented in the Selected Populations Held Constant Section beginning on page 19 of this report. Below is the notation of the general formula that has been adjusted to hold selected populations constant.

$$Population_{projected} = (Population_{current} - Population_{select\ population}) \times (Survival\ Rate \times Net\ Migration\ Rate) + (Population_{select\ population})$$

Once the data for each of the components had been developed, it was a relatively straightforward process to apply the cohort-component method and produce the projections. For each projection year, the current population for each municipality was disaggregated by sex and five year age groups (age 0 to 4 through 85 and over). The population under age 5 was created by applying the appropriate age specific fertility rates to the females of childbearing age. The number of births by sex were then survived forward and exposed to the appropriate migration rates to yield the population under age 5. The next step was to survive each of the current age/sex cohorts forward five years using the pertinent survival rates. The migration of the population was accomplished by applying the appropriate age specific municipal net migration rates to the survived population in each municipality. The entire process was repeated for each five year period of the projection.

Definitions of Cohort-Component Method

Base Population

The base population of these projections is the April 1, 1980 resident population of Connecticut municipalities by sex and five year age groups as provided by the U.S. Bureau of the Census.

The population data shown in this report are for the resident population of each municipality. Resident population includes persons in households (i.e. persons in single-family, multi-family, apartments, condominiums, etc.) and group quarter population (i.e college students, military, prisoners, persons in nursing homes, and other institutionalized persons), where they reside. Armed Forces overseas are excluded.

The 1980 decennial census figures have an April 1st reference date; the 1985 estimates and all projections have a July 1st reference date. Adjustments were made in the birth, death and migration data to compensate for the differences in these reference dates.

Natural Change

Natural change is the net effect of the number of births less the number of deaths for a specific geographic area (i.e. municipality) over a set time span. In these projections, the two components of natural change, births and deaths, are handled separately to keep the assumptions related to births, which apply only to females between the ages of 10 through 54, separate from deaths which apply to all cohorts.

Births and Fertility Rates

Data from 1980 to 1987 for resident live births were provided by the Connecticut Department of Health Services. These were used to calculate fertility rates for women of child bearing ages (10 to 54) for each municipality over five year intervals.

The fertility rates used in projecting births were calculated by using actual births between July 1, 1982 and June 30, 1987 as the numerator with the associated OPM July 1, 1985 female population estimate as the denominator. There were separate fertility rates calculated for the 9 childbearing cohorts. The fertility rates used are considered to be five year fertility rates. However, the term used will simply be "fertility rate." Note that there are fertility rates to determine the number of males to be born and separate rates to project the number of females to be born. Below is the expression just for female births.

$$\textit{Fertility Rate for Female Births} = \frac{\textit{Number of Female Births by Cohort of Mother}_{(1982\text{-}1987)}}{\textit{Estimate of Women by Childbearing Cohort}_{(1985)}}$$

Deaths and Survival Rates

Actual figures from 1980 to 1987 on resident deaths were provided by the Connecticut Department of Health Services. These were used to calculate survival rates for each of the 36 cohorts for each municipality. A five year survival rate can be considered to be the percentage of people who will survive the next five years. In this report it is understood that a "survival rate" is for a five year period. Survival rates are calculated by the following equation.

$$\textit{Survival Rate} = 1 - \textit{Death Rate}$$

Therefore, it is necessary to first determine the death rate. The death rate can be expressed as:

$$\textit{Death rate} = \frac{\textit{Number of Deaths by Cohort}_{(1982\text{-}1987)}}{\textit{Population Estimate by Cohort}_{(1985)}}$$

The survival rates for each of the 36 cohorts used in the projections are defined as follows. The numerator is the sum of all deaths for every cohort over a five year period (July 1, 1982 to June 30, 1987). The denominator is the July 1, 1985 population estimate for each cohort. Once the death rates were calculated they were subtracted from 1 to determine the survival rates.

Migration and Net Migration Rates

In order to select the proper indicators of migration for these population projections, the following data conditions had to be met:

(a) available for each municipality in Connecticut,
(b) available on an annual basis beginning with 1980,
(c) able to be separated into five year age/sex cohorts, and
(d) provide a direct measure of individuals moving.

These four criteria eliminated many possible migration indicators. Three data sources provided what was required. However, they did not provide why people moved, or how often people moved. Instead, they provided the net effect of people's movements in, out and within Connecticut municipalities. In other words, three data sources were identified to produce "net migration" figures by age/sex cohort for every municipality on an annual basis. They are: changes in public and private school enrollment, changes in the number of driver licenses, and changes in medicare enrollments.

A net migration rate is very different from either a fertility rate or a survival rate in that it represents a change between two points in time, rather than an accumulation of births or deaths throughout a set time period.

Net migration rates, regardless of their source, are calculated in the same manner. Migration rates indicate a change in peoples movements over time. To measure this change, two different population estimates are compared. The numerator is the 1987 population estimate. The denominator contains an estimate five years earlier; 1982. (Note that 10 to 14 year olds in 1987 were only 5 to 9 years of age in 1982). Finally, any differences between the 1987 estimate and the 1982 estimate must be caused by either people moving (migration) or people dying. Since deaths are already handled through survival rates, these same survival rates must be factored out of the migration rate. This is done by having the survial rate as part of the denominator.

The above description can be expressed as follows using the 5 to 9 age group which have been survived to age group 10 to 14, as an example:

$$Migration\ Rate_{(10\text{-}14)} = \frac{1987\ Population\ Estimate_{(10\text{-}14)}}{1982\ Population\ Estimate_{(5\text{-}9)} \times Survival\ Rate_{(5\text{-}9)}}$$

The specific net migration indicators are discussed below.

1985 Population Estimates

In order to calculate fertility, survival and net migration rates, there needs to be a population estimate that is used for the base (the denominator) of each rate. The rates that were developed using data between 1980 and 1985 used the age and sex specific 1980 decennial census data as a base. When calculating rates using the 1982 to 1987 data, it became necessary to update the base year to 1985 (this is because 1985 is the midpoint between 1982 and 1987). Since the data collected to measure the differences in peoples migration, looked at changes in population estimates, it was decided to use the same indicators (school enrollments, drivers licenses, and medicare enrollments) to estimate the 1985 municipal populations by age and sex groups. The same process was used to develop the 1982, 1985 and 1987 population estimates. The 1982 and 1987 estimates were used to identify migration patterns. The 1985 population estimate was used as the base for all rates. An example of how these estimates were prepared is located on page 17.

Net Migration - School Enrollment

Changes in the public and private school enrollment for grades K to 4 were used as net migration indicator for children ages 0 to 4 and 5 to 9. The changes in school enrollments for grades 5 to 9 were used as a net migration indicator for children ages 10 to 14. These data were provided by the Connecticut State Department of Education for years 1980 to 1987. All enrollment data were identified by the place of residence of the child regardless of where they attended school.

The school enrollment data was not separated into males and females, therefore it was assumed that there would be a 50/50 split between both categories. This was based upon the fact that there is no discernible information that indicates that female children would survive differently than male children until they reach their late teens. Approximately 71% of the children under the age of 15 were enrolled in grades K to 9 in 1980. This means that the remaining 29% of the children were considered to move in similiar patterns as those children enrolled in grades K to 9.

Net Migration - Licensed Drivers

Changes in the number of licensed drivers (excluding public service, motorcycle, and other special licenses), were used to indicate the migration of persons 16 to 64 by municipality. These data were provided by the Connecticut Department of Motor Vehicles for years 1980 to 1987.

Approximately 92% of Connecticut residents between the ages of 16 to 64 had a drivers license in 1980. This means that approximately 8% of the population between ages 16 and 64 were not part of the migration patterns identified from the drivers license data. Those persons without drivers licenses were assumed to move in similiar patterns as those who did have a drivers license.

The drivers age was used to aggregate the data into five year age groups for each municipality for both males and females. Municipal data were available for 1981 through 1987. Statewide figures were available from 1980 to 1987. Using the statewide change between 1980 and 1981, each of the 1981 municipal figures were adjusted back to a reasonable 1980 municipal figure for each age group.

In addition, there were years when the DMV changed its collection and reporting procedures, thereby necessitating an adjustment of each years' data so that it accounted for all of the licensed drivers listed in the statewide report even if the town of residence was not properly identified.

The licensed drivers data for years 1981 to 1983 was arranged by zip code rather than municipality. A zip code conversion method was developed by this office (OPM) which was based upon 1980 decennial census population data for municipalities and corresponding 1980 zip code populations. The proper allocation of zip codes to town of residence was done arithmetically and with numerous consultations with U.S. Postal Officials. Licensed drivers data for years 1984 to 1987 was reported by municipality according to a DMV zip code conversion methodology, however, upon closer analysis it was determined that DMV conversion method between zip codes and towns was not consistent to the OPM method. This meant identifying all differences between the two methods, then the data were adjusted and made consistent with the licensed drivers data from 1981 to 1983.

School enrollment data for fifteen year olds was not used due to the varying ages when students go into high school and large variations among municipal drop-out rates. Therefore, the migration of 15 years of age was assumed to be the same as those in ages 16-19, even though the drivers license data begins at age 16.

Net Migration - Medicare Enrollment

Changes in the number of persons who are enrolled in medicare was used to indicate migration for persons 65 years of age and older. This data was provided by the U.S. Health Care Financing Administration for years 1980 to 1987. The medicare data identifies persons enrolled in the medicare program by five year age group beginning with ages 64 to 69 through ages 85 and older for males and females by zip code. By using the same zip code conversion process developed for the licensed drivers data, town of residence data was developed. Approximately 99% of persons 65 and older in 1980 were enrolled in the medicare program in Connecticut. Therefore, the medicare data accounts for nearly all of the movements of those persons 65 years of age and older.

Assumptions, Procedures and Examples

The basic assumption behind this method is that there is a direct linear relationship between the number of persons in a specific age/sex group and the number of deaths, migration and births associated with that same age group. These relationships are represented in the form of rates.

Births and Fertility Rates

Fertility rates are applied to the number of women who pass through the associated age group which generates an estimate of the number of male and female children born within each five year time span. This process is repeated for each of the child bearing age groups throughout the entire projection period.

These five year fertility rates are held constant for each female age group during childbearing years (which are between the ages of ages 10 to 54) for each municipality. However, this does not mean that the same number of children will be born in each municipality throughout the projection period. Rather, variations in the number of births occur because the number of women who pass through each five year age group is different.

For example, the 1982-1987 fertility rate in Mansfield is 0.291 for women between the ages of 25 and 29. In 1985 there were 720 women between 25 and 29. In 1990 there were 620 women of that age group, and in 2000 there were 770. The number of births for each of these time periods would be 209, 180, and 224 respectively. Thus the number of births vary over time due to the number of women in that specific age group even through the fertility rate remains constant.

After the fertility rates have been applied and the number of male births and female births projected, the number of births are placed into the appropriate 0 to 4 age group for each municipality. Then survival and migration rates are applied to the 0 to 4 age group.

As a result, the number of children in the 0 to 4 age group may be different than the number of births over a five year period. For example, in Mansfield between 1985-1990 there would be 640 births. However, the 1990 projected population of the first age group (0 to 4) is 630. The difference is the result of 10 less children ages 0 to 4 moving out of Mansfield than moving in between 1985-1990. (Note, it was assumed there would not be deaths during this time period.)

Deaths and Survival Rates

It is assumed that the survival rates calculated from the 1982 to 1987 death data will remain constant throughout the entire projection period.

As expected, the death rates and resulting survival rates vary considerably with age. For example, in Mansfield there was 1 death between 1982 and 1987 for males ages 15 to 19; there were 27 deaths for the same period for males ages 75 to 79. The survival rates for these two cohorts are 0.996 and 0.565, respectively.

Interpreting these survival rates indicates that over 99% of the males ages 15 to 19 will reach the next cohort (20 to 24), while 56% of the males ages 75 to 79 will survive to the next cohort (80 to 84).

Migration and Net Migration Rates

Each one of the three migration indicators accounted for only a portion of each municipal population in specific age groups. What became evident, is that these indicators varied in their ability to cover the specific age groups. The development of coverage rates which varied for each age group and for each municipality provided the necessary adjustments of the migration indicators.

In order to calculate the migration rate as described, it became necessary to produce 1982 and 1987 population estimates in five year age/sex cohorts for each municipality. This was done by examining the relationship between the 1980 migration indicator and the 1980 decennial census figure for each cohort for each municipality. Once that relationship was developed, it was assumed to be held constant from 1980 through 1987, thereby allowing that relationship to apply to the 1982 and 1987 migration indicator. This also applies to the 1985 population estimate used for the base of each rate, see page 14. This relationship has been termed the "coverage ratio".

In Middletown, for example, in 1980 there were 738 persons enrolled in Medicare between the ages of 75 to 79 and 527 persons between the ages of 80 to 84. The 1980 decennial census figures for the same age group show 753 persons and 577, respectively.

Example	Age Group	(A) 1980 Medicare Enrollment	(B) 1980 Census	(B/A) Coverage Ratio
Middletown	75-79	738	753	1.020
	80-84	527	577	1.095

By dividing the Medicare enrollment into the 1980 decennial census population for the same age group this will calculate the coverage ratio. Then the coverage ratio is applied to the 1982 and 1987 Medicare enrollment to produce population estimates for those years as shown below.

Example	Age Group	Coverage Ratio	1982 Medicare Enrollment	Calculated 1982 Pop. Ests.	1987 Medicare Enrollment	Calculated 1987 Pop. Ests.
Middletown	75-79	1.020	838	855	1,031	1,052
	80-84	1.095	502	550	601	658

The coverage of Medicare data was the best, at approximately 99% statewide. Licensed drivers data varied between 75% to 105%. (It is possible to have more licenses than people. This is due to the fact that many other states do not notify Connecticut when a person moves out-of-state and obtains a new license, or someone dies and the Connecticut license continues to be valid for up to four years). In those cases where the coverage is greater than 100%, the coverage ratio will reduce the number of licenses accordingly. The school enrollment data coverage was about 71%.

These migration figures are measures of the net effect of people moving, rather than a measure of the movement itself. It offers no reasons as to why people move nor does it provide any insight to the inter-relationship with housing. This migration methodology looks only at the results after people have moved by specific age groups, by male and female groups and by individual municipalities throughout Connecticut.

When analyzing migration, it is important to look at figures in five year intervals. For example, in 1980 there were 587 children ages 5 to 9 in Mansfield, in 1985 there were 650 children ages 10 to 14. The 63 difference is the result of 2 children dying and 61 more children ages 5 to 9 moved out than moved in to Mansfield.

Adjustment of Migration Rates

The migration rates for the 1985 to 1990 projection period are based upon the migration indicators previously mentioned which were for the period of 1982 to 1987.

The migration rates for 1990 to 1995 were adjusted slightly to reduce extremely high in or out migration rates, as it was felt that any extreme values would not continue. These rates were brought closer to the average of the migration rates within each municipality using the following separate process for males and females: temporarily removing the highest and lowest migration rates among the eighteen age cohorts; averaging the remaining rates; and then adjusting all of the rates, including the extremes, so that they will be closer to the calculated average.

Another adjustment was made to the migration rates between 1995 and 2000. This adjustment took the adjusted 1990 to 1995 rates and applied the square root to each rate. As the projection years move further from the base year, it is assumed that the extreme and moderate migration rates will tend to move toward a migration rate of 1.0 (which is equal to a zero migration). Thus, the effect of migration will be less.

Upon review of a number of municipal projections, an unusual situation occurred in the overall affects of migration. Specifically between 1980 and 1985, some municipalities had a substantial inmigration and yet between 1985 and 1990 this would change to a substantial outmigration. When migration trends change direction, the basis to continue either trend could not be determined.

Therefore, an average of the 1980 to 1985 migration rate and the 1982 to 1987 migration rate was utilized. This averaging technique affected 42 municipalities and was applied before any of the above mentioned adjustments took place.

Selected Populations Held Constant

This report presents population projections of the resident population, which is comprised of two groups. The first and most common group are those persons in households. Persons in households are people living in a housing unit (e.g., single and multi-family houses, apartments, condominiums, etc.) The second group are those persons in group quarters. These people live in a variety of settings, such as college dormitories, state or federal prisons, hospitals, nursing homes, motels, hotels, convents, etc.

Certain institutions within Connecticut have populations that do not change their age makeup. For example, the University of Connecticut located in Mansfield will always have a large concentration of 15 to 19 through 30 to 34 year olds in dormitories or in off campus housing. The majority of these people will not continue to reside in Mansfield, as they get older. Therefore, the population projection methodology needs to hold these selected age and sex groups constant within Mansfield.

All persons in group quarters were held constant according to their age and sex identified in the 1980 decennial census. The exception being those persons over 80 years of age in group quarters. These older people were small in number in most municipalities and thus it was easier to include them within the general projection methodology.

Those college students that lived off campus (not in dormitories) had similiar migration patterns to those students who did live in college dormitories. These off campus students are concentrated in housing in the vicinity of the college campus, and year after year the students with similiar ages live in those areas.

In consultation with the Connecticut Department of Higher Education, colleges were identified that had students living off campus in concentrated areas. This does not include students who are residents of a municipality and commute to class. The number of persons between 15 to 34 that are above the average number of persons in the non-college age groups, and who live in households, were then identified. These persons were considered off campus college students and held constant if they lived in census tracts that either contained or were in the vicinity of one of the identified colleges.

An additional population group that was selected to be held constant was the military and their families that live off base. There were over 14,000 persons in the Armed Forces (military personnel) in Connecticut in 1980, almost 13,000 of whom lived in New London County. Upon a closer look, less than half of the military lived in group quarters for which adjustments had already been made. Approximately 6,000 military personnel lived off base (not in group quarters), and were located in Groton, New London, Ledyard and Norwich.

A determination was made that both the military personnel and their families age and sex composition should be held constant. Individual neighborhoods (or block groups) were identified where the military personnel were concentrated and an assumption was made that everyone in that neighborhood was either in the military or a member of a military family. Thus, the entire age and sex composition of the neighborhood was held constant.

The last step was to combine all three types of populations to be held constant (group quarters, college students off campus, and military and their families that live off base) by municipality.

These municipal aggregations were then subtracted from the municipalities' total population by specific age group before any survival or migration rates were applied. After these rates were applied to the "non-selected" population, the selected populations were added back to form new municipal totals. However, birth rates were applied to the entire female population in childbearing ages, including women in the populations that were held constant (i.e. group quarters, college students off campus and military personnel and their families). This is due to the fact that birth records indicate all births, regardless of whether the mother is in a special population group or not. TABLE 5, which follows, provides a listing of the number of persons held constant by municipality.

Limitations, Accuracy and Rounding

As mentioned in the methodology, the basic underlying assumption with these population projections is that IF the birth, death and migration trends identified between 1980 and 1987 CONTINUE, then the projections show what MAY occur demographically in the future.

There are numerous limitations associated with that assumption. The following is not an exhaustive list, but rather some of the more apparent limitations that should be kept in mind when using these population projections.

It is very likely that these trends will not continue, especially for the next twenty-one years. Some of the reasons why they will not continue are a change in the economy, changes in zoning, limitations on developable areas, new or expanded transportation networks and commuting patterns. These are all reasons why the demographic trends will change. However, changes in these trends is much more difficult to predict than the projecting a population using identified trends.

The accuracy of these projections is directly dependent on how accurate the birth, death and migration trends depict future trends. Without describing all of the adjustment procedures in detail, the following review should be helpful in gathering insight into what may be considered accurate and what could be considered further limitations.

The birth and death data are actual occurrances for each municipality between 1980 and 1987. These are considered very reliable and accurate. However, since the migration of women of child bearing ages significantly affects the number of births, the migration may make the projected numbers of births less accurate.

As implied above, migration is the most difficult trend to measure and therefore, is the least accurate component to these projections. Among the three sources of migration data, the Medicare enrollment data for those ages 65 and older, is considered to be very accurate. This is because almost 99% of Connecticut's 65 and older population were enrolled in the Medicare program.

The school enrollment data is considered accurate for those children attending school. However, the enrollment data was arranged by grades instead of by the age and sex of the children. Therefore, some inaccuarcies may be part of the data when students do not progress to the next grade in one year. The lack of data for those students who drop out of school as well as pre-school children, forced the use of migration trends for those in school to be the same as those children out of school. The drop-out issue is more severe in the major cities and should be taken into consideration when analyzing projected school age children.

The drivers license data covered about 92% of the 15 to 64 population. The overall accuracy of this data is less than either school enrollment or Medicare enrollment, yet the inaccuracies seem to affect selected municipalities. Again, without going into the various adjustments that were made to improve the drivers license data, some specific concerns still remain.

Within the major cities, there are large numbers of persons who do not have drivers license. It was assumed that their migration patterns would be similiar to those who did possess a drivers license. Studies show that persons receiving Aid to Families with Dependent Children (AFDC), many of whom do not have a drivers license, are very mobile. The Connecticut Department of Income Maintenance records indicate that 1/3 of the AFDC clients move each year. This seems to indicate there may be different migration patterns of those who do not have a drivers license than those who do. In addition to this possible discrepency, the influx of immigrants into Connecticut cities and towns is not captured by drivers license data. Licensing usually does not occur until some period of time has transpired, if licensing occurs at all. Both school enrollment and medicare data capture the influx of immigrants more immediately due to immigrant participation in these programs.

In general, the population projections for 1990 and 1995 are considered the most accurate. Subsequent projections are successively less accurate, to the point where the 2010 projections should be used with caution and only as a rough indicator of what the populations may be.

Rounding was introduced to remind the user about the limitations of the projections, as well as removing any false sense of accuracy. The 1980 figures are actual counts from the 1980 decennial census and are not rounded. All other figures are rounded. Total figures are rounded to the nearest 50. Figures for individual cohorts (age/sex groups) are rounded to the nearest 10.

Summary of Review Comments

The Technical Advisory Committee (TAC) for Population Projections was formed by the Office of Policy and Management to offer advice and review all aspects of the production of new population projections. As a result of this collaboration, a new methodology was developed and accepted. This new methodology is flexible so that it can incorporate new data, new trends and new assumptions. It has been suggested that the projections be updated on a frequent basis thereby keeping the projections up-to-date.

The TAC was made up of researchers and planners from seven state agencies and one representative from the regional planning organizations. Bi-monthly meetings covered data sources, methodology, adjustments to the data, reasonableness and usefulness of the projections, report content and layout. However, the single most helpful function the TAC provided was alternative approaches to the methodology and then collectively deciding which approach to use.

In addition to the TAC assistance there were two major efforts to solicit review comments on the report and the population projections themselves. The first review was conducted by the regional planning organizations. Over a two week period, substantive comments were received and acted upon. As a result of this initial review, adjustments were made to the methodology that affected most municipal projections.

In the second review, the population projections were again distributed to the TAC and the regional planning organizations. The regional planning organizations were requested to solicit comment from municipalities. As a result, further changes were made to the methodology that affected over 40 municipal projections. The following Table provides a summary of the comments and resolutions.

TABLE 6

TABLE 6
(Continued)

Legend

Type of Comments Received:

1 Projections were too high - 11
2 Projections were too low - 42
3 Method should include housing units as a factor - 25
4 Explain methodology in detail - 20
5 1990 Projections not consistant with 1988 Department of Health Estimates - 20
6 Review period was too short - 23
7 Agreement with projections - 4
8 Improper handling of off campus students - 4
9 Improper handling of off base military and their families - 4
10 Wait for the 1990 Census data to become available - 11

Total Comments received - 58

OPM's Responses:

A. Issues or errors were identified and corrected - 19
B. Methodology, assumptions and input data was reviewed with the municipality in detail - 34
C. Migration data was re-checked and verified - 39

Final Status:

Satisfied — After the indicated explanations, adjustments and verifications were made by OPM, the commenting agency was satisfied with projections. - 34

Not Satisfied — After the indicated explanations, adjustments and verifications were made by OPM, the commenting agency was not satisfied with projections. Some of the commentary concerned projections for varying time periods which were believed to be too high, others were believed to be too low. For those municicpalities that remain not satisfied, data with age and sex detail could not be identified; which could further assist in addressing and possibly resolving the expressed concerns. - 10

Acknowledged — Issues were identified which were limited in the overall effect on the projections. At this time OPM is not in a position to make these limited adjustments. However, these issues will be factored into the next update of these projections. - 14

Acknowledgements

The Technical Advisory Committee members are listed below. These individuals have been very helpful in reviewing, discussing and clarifying each step in preparing this latest set of population projections. This included the development of a new projection methodology, providing greater understanding of other state agency uses of the projections, along with a better understanding of the assumptions and limitations of these projections.

Another important role of this Committee was to foster a better understanding of the data requirements of the projection model and make their agency population projection needs known to the Office of Policy and Management so that subsequent updates will be more beneficial. The time committment of the Committee members is greatly appreciated along with their many questions and suggestions.

Technical Advisory Committee

Name	Responsibility Area	State or Regional Agency
Sandy Bergin	Housing Planning and Research	Housing
Maria Buatti	CHRIS Coordinator	Policy and Management
Lila Kove	Child Service Planning	Children & Youth Services
Loretta Polka	Regional Planning	South Central COG
Peter Prowda*	Educational Research & Evaluation	Education
Joseph Spragg	Transportation Planning	Transportation
Leah Weintrub*	Health Policy and Planning	Health Services
Andrew Wright	Planning for Elderly Services	Aging

In addition to the Technical Advisory Committee, others were also involved who played an important role in providing data and/or comments on our new methodology, along with general guidance and support. These persons are acknowledged below.

Additional Support Provided by

Name	Responsibility Area	Agency
15 Directors	Regional Planning	CT Regional Planning Org's
James Clark*	Driver Licensing - Data Proc.	CT Dept. of Motor Vehicles
Ellen Cromley	Geography Department	University of Connecticut
Peter Halverson	Geography Department	University of Connecticut
Lawrence Hammell	Regional Planning	NY Metro Trans. Council
Martha Highsmith	Research & Planning	CT Dept. of Higher Education
Robert MacLagger	Service Planning	Metro North Rail Road
Michael McMullen*	Medicare Information	U.S. Health Care Fin. Admin.
Jan Miller	Planning & Evaluation	CT Dept. of Income Maintenance
Paul Pochran*	Driver Licensing - Data Proc.	CT Dept. of Motor Vehicles
Gerald Stowell	Management & Justice Planning	CT Office of Policy & Mgmt.
Charles Vidich*	Facilities & Planning	U.S. Postal Service
Signe Wetrogan	Population Projections	U.S. Bureau of the Census

* Data was supplied by these agencies.

Additional Projection Information and Services Available

Additional copies of this report are available for $10.00. The entire report is also available on diskette for $20.00. The report in either format is available from the Connecticut Census Data Center.

The fertility, survival and migration rates utilized in the preparation of the age and sex distributions are also available on diskette, which is available from the Connecticut Census Data Center. The rates are broken into five-year age groups by sex for each municipality. The entire set of fertility, survival and migration rates cost $20.00.

A necessary step in preparing these projections involved reassigning zip coded data to the appropriate municipality. The zip code conversion process developed is one of the most extensive conversions available for Connecticut using ratios of zip code population to municipal populations. This conversion process is available on diskette for $20.00 upon request.

Population estimates by age and sex for each municipality are available on diskette for years 1981 to 1987. The 1985 population estimates were used as the base for all of the municipal fertility, survival and migration rates. These population estimates are based upon the same methodology as the projections contained in this report.

Any portion of this printed report may sent via facsimilie at a cost of $1.00 per page. Please contact the Connecticut Census Data Center to make the necessary arrangements.

All inquiries involving explanations of the projection methodology, ordering reports or files, or specific questions regarding the population projections will be handled by the Connecticut Census Data Center. Below is the address and phone number for assistance. Please note that all of the above mentioned products are subject to sales tax (unless the organization is tax exempt) in addition to a fee for postage and handling. Please use the attached Order Form and enclose payment to expedite your order.
